When I first started testing, my results were completely skewed because the way I was generating my random number was making it the best case scenario for the linear search. This created an anomaly that made it so my Linear search was actually faster a majority of the time because the number it was looking for was in the beginning of the list. However, when I started putting larger numbers in to search for (which is depicted in the graph), I saw drastic change in search times. Binary far surpassed the search times that Linear search could produce. I was and currently am quite impressed with how much faster it actually is.
